

# STORY 2 — Technical Implementation Using Power BI

## 1. Power BI Desktop – Data Import & Setup

- Imported dataset from Excel (Sheet1)
- Verified columns for Vehicle ID, Driver Name, Distance, Revenue, and Trips
- Ensured structure was clean before transformation

## 2. Power Query – Transformations Applied

- Removed unnecessary columns
- Changed data types (Distance → Decimal, Revenue → Decimal, Trips → Whole Number)
- Removed duplicates
- Filtered blank values
- Cleaned and trimmed text columns
- Renamed columns for clarity

## 3. Power Pivot – Data Modeling

- Number of tables: 1 (single dataset)
- No additional dimension tables required
- No relationships needed due to single-table model
- Measures created using DAX for KPIs

## 4. Power View – Visualizations Used

- Bar Chart – Vehicle performance comparison
- Column Chart – Driver performance analysis
- Pie/Donut Chart – Driver contribution percentage
- Card Visual – Total revenue KPI
- Filters/Slicers – For interactive analysis

## 5. DAX Measures Created

Total Distance = SUM(Sheet1[Distance (km)])

Total Trips = SUM(Sheet1[Trips])

Total Revenue = SUM(Sheet1[Revenue])

Purpose: To calculate aggregated KPIs consistently across the dashboard.

## 6. Final Output

- Total Pages: 1
- Key Dashboards:
  - Vehicle-wise performance
  - Driver-wise comparison
  - KPI card for revenue
- Final Insights Summary:

The fleet shows clear performance leaders. Underutilization patterns and uneven driver performance highlight optimization opportunities.
